SQL Cheat Sheet: Accessing Databases using Python

SQLite

Topic	Syntax	Description	Example
connect()	sqlite3.connect()	Create a new database and open a database connection to allow sqlite3 to work with it. Call sqlite3.connect() to create a connection to the database INSTRUCTOR.db in the current working directory, implicitly creating it if it does not exist.	<pre>1. 1 2. 2 1. import sqlite3 2. con = sqlite3.connect("INSTRUCTOR.db") Copied!</pre>
cursor()	con.cursor()	does not exist. To execute SQL statements and fetch results from SQL queries, use a database cursor. Call con.cursor() to create the Cursor.	<pre>1. 1 1. cursor_obj = con.cursor() Copied!</pre>
execute()	cursor_obj.execute()	The execute method in Python's SQLite library allows to perform SQL commands, including retrieving data from a table using a query like "Select * from table_name." When you execute this command, the result is obtained as a collection of table data stored in an object, typically in the form of a list of lists.	<pre>1. 1 1. cursor_obj.execute('''insert into INSTRUCTOR values (1, 'Rav', 'Ahuja', 'TC Copied!</pre>
fetchall()	cursor_obj.fetchall()	The fetchall() method in Python retrieves all the rows from the result set of a query and presents them as a list of tuples.	<pre>1. 1 2. 2 3. 3 4. 4 5. 5 1. statement = '''SELECT * FROM INSTRUCTOR''' 2. cursor_obj.execute(statement) 3. output_all = cursor_obj.fetchall() 4. for row_all in output_all: 5. print(row_all)</pre>
fetchmany()	cursor_obj.fetchmany()	The fetchmany() method retrieves the subsequent group of rows from the result set of a query rather than just a single row. To fetch a few rows from the table, use fetchmany(numberofrows) and mention how many rows you want to fetch.	Copied! 1. 1 2. 2 3. 3 4. 4 5. 5 1. statement = '''SELECT * FROM INSTRUCTOR''' 2. cursor_obj.execute(statement) 3. output_many = cursor_obj.fetchmany(2) 4. for row_many in output_many: 5. print(row_many) Copied!
read_sql_query() read_sql_query()		read_sql_query() is a function provided by the Pandas library in Python, and it is not specific to MySQL. It is a generic function used for executing SQL queries on various database systems, including MySQL, and retrieving the results as a Pandas DataFrame.	<pre>1. 1 1. df = pd.read_sql_query("select * from instructor;", conn) Copied!</pre>
shape	dataframe.shape	It provides a tuple indicating the shape of a DataFrame or Series, represented as (number of rows, number of columns).	<pre>1. 1 1. df.shape Copied!</pre>
close()	con.close()	con.close() is a method used to close the connection to a MySQL database. When called, it terminates the connection, releasing any associated resources and ensuring the connection is no longer active. This is important	1. 1 1. con.close() Copied!

                                                                              3. 3
                 df.to_sql('table_name',
index=False)
                                                DataFrame to a SQL
to_sql()
                                                                              1. import pandas
                                                database. It allows to take
                                                                                    = pandas.read_csv('https://data.cityofchicago.org/resource/jcxq-k9xf.csv
                                                data from a DataFrame

    df.to_sql("chicago_socioeconomic_data", con, if_exists='replace', index=Fal

                                                and store it structurally
                                                                           Copied!
                                                within a SQL database
                                                table.
                                                read_sql() is a function
                                                provided by the Pandas
                                                library in Python for
                                                                              1. 1
                                                executing SQL queries
                                                                              2. 2
                                                and retrieving the results
                 df = pd.read_sql(sql_query,
                                                                              1. selectQuery = "select * from INSTRUCTOR"
read_sql()
                                                into a DataFrame from an
                 conn)
                                                                              2. df = pandas.read_sql(selectQuery, conn)
                                                SOL database. It's a
                                                convenient way to
                                                                            Copied!
                                                integrate SQL database
                                                interactions into your data
                                                analysis workflows.
```

Db2

Topic	Syntax	Description	Example
connect()	<pre>conn = ibm_db.connect('DATABASE=dbname; HOST=hostname;PORT=port;UID=username; PWD=password;', '', '')</pre>	ibm_db.connect() is a Python function provided by the ibm_db library, which is used for establishing a connection to an IBM Db2 or IBM Db2 Warehouse database. It's commonly used in applications that need to interact with IBM Db2 databases from Python.	1. 1 2. 2 3. 3 4. 4 1. import ibm_db 2. conn = ibm_db.connect('DATABASE=mydb; 3. HOST=example.com;PORT=50000;UID=myuser; 4. PWD=mypassword;', '', '') Copied!
server_info()	<pre>ibm_db.server_info()</pre>	ibm_db.server_info(conn) is a Python function provided by the ibm_db library, which is used to retrieve information about the IBM Db2 server to which you are connected.	<pre>1. 1 2. 2 3. 3 4. 4 1. server = ibm_db.server_info(conn) 2. print ("DBMS_NAME: ", server.DBMS_NAME) 3. print ("DBMS_VER: ", server.DBMS_VER)</pre>

close()

about:blank

4. print ("DB_NAME: ", server.DB_NAME)

Copied!

con.close() is a method used to close the connection to a db2 database. When called, it terminates the connection, releasing any associated resources and ensuring the connection is no longer active. This is important for managing database connections efficiently and preventing resource leaks in your db2 database interactions.

ibm_db.exec_immediate() is a Python function provided by the ibm_db library, which is used to execute an SQL statement immediately without the need to prepare or bind it. It's commonly used for executing SQL statements that don't require input parameters or don't need

to be prepared in advance.

1. 1 con.close() Copied!

1. 1 2. 2

Lets first drop the table INSTRUCTOR in case it exists from a p
 dropQuery = "drop table INSTRUCTOR"
 dropStmt = ibm_db.exec_immediate(conn, dropQuery)

Copied!

sql_statement = "SQL statement goes

exec_immediate() stmt = ibm_db.exec_immediate(conn, sql_statement)

con.close()
